Keywords: entomological net, Ezareni, Coccinellidae

ABSTRACT

The purpose of this research is that to identify the useful entomofauna of Coccinellidae (Coleoptera-Coccinellidae) within the maize crop that has been taken into this study. The researches were carried out within Ezareni station which belongs to University of Applied Sciences of Iasi, Romania. The biological material was sampled by the mean of entomological net from May 12th to June 19th of 2018. In total, 7 samples were made. In order to collect insects, 10 plants were hiten for one minute each one. After finishing the experiments within the field, the insects were brought into the Laboratory of Entomology, in order to be counted and identified. From the Coccinellidae family, the most dominant species were: *Coccinella septempunctata* (32 samples) and *Adalia bipunctata* (27 samples) and *Harmonia axyridis* (16 samples).

INTRODUCTION

Coccinellidae family has species of round or oval species, almost hemispherical, with spots on the wings with color spots and contrasting patterns. The most species of *Coccinellidae* are beneficial predators which prefer the aphids as main feed.

According to the author (Foltz, 2002), there are more than 5000 species all around the world. The most representative species of the *Coccinellidae* family are: *Coccinella 7-punctata*, *Adonia variegata*, *Chilocorus bipustulatus*, *Adalia bipunctata*.

The insects of *Chrysomelidae* family are commonly known as leaf beetles and include more than 50000 species, making up one of the most common encountered of all beetle families. Many species represent serious pests of cultivated plants (e.g. *Leptinotarsa decemlineata*-Colorado potato beetle).

MATERIAL AND METHOD

In order to carry out the researches, the insects were sampled from one station (Ezareni) from Iasi county, which belongs to University of Applied Sciences of Iasi, Romania, by using the entomological net method. The experiments took place from May to June

of 2018. There were 7 samples carried out in total, the first one being at 12th of May and the last one being at June 19th of 2018. 10 plants were hiten for one minute each one.

RESULTS AND DISCUSSIONS

The samples of the biological material were carried out at the following dates: 12.05, 16.05, 22.05, 29.05, 05.06, 12.06, 19.06 of 2018.

The situation looks as follows (**table 1**):

12.05: there were 2 samples identified belonging to *Coleoptera* order, families: *Cerambycidae* (1) and *Chrysomelidae* (1). There was no sample belonging to *Coccinellidae* family.

16.05: there were 5 samples identified from *Coleoptera* order, families: *Coccinellidae* (3), *Cantharidae* (1) and *Chrysomelidae* (1);

22.05: there were 10 samples identified from *Coleoptera* order, belonging to the following families: *Chrysomelidae* (1) and *Coccinellidae* (9);

29.05: there were 37 samples identified from *Coleoptera* order, families: *Chrysomelidae* (7), *Cerambycidae* (2) and *Coccinellidae* (28);

05.06: there were 29 samples identified from *Coleoptera* order, belonging to the following families: *Chrysomelidae* (2), *Cerambycidae* and *Curculionidae* (each 1 sample) and *Coccinellidae* (25);

12.06: there were 19 samples identified from *Coleoptera* order, that belong to *Chrysomelidae* family.

19.06: there were 77 samples identified from *Coleoptera* order, belonging to the following families:

Coccinellidae (63) and *Chrysomelidae* (14).

Situation on families to which belong the sampled *Coleopteras* species looks as follows: (**table 2**)

Results regarding structure of coccinelids (*Coleoptera-Coccinellidae*) sampled from the wheat crop looks as follows (**table 3**):

The species of *Coccinellidae* represent a procent of 71.51% of total number of *Coleopteras* (179) (**table 4**).

CONCLUSIONS

- The coccinelids species have been sampled at 5 of a total of 7 samples, with a total of 128 samples and representing 71.51% from the total number of *Coleopteras* (179);

- It was identified a number of 8 species, the most abundant species being *Coccinella septempunctata* (32 samples), followed by *Adalia bipunctata* (27 samples) and *Harmonia axyridis* (16 samples).

- *Cantharidae* species have been sampled at one of all 7 samples, with a total of 1 sample;

- *Cerambycidae* species have been sampled at three of all 7 samples, with a total of 4 samples;

- *Chrysomelidae* species have been sampled at all 7 samples, with a total of 45 samples;

- *Curculionidae* species have been sampled at one of all 7 samples, with a total of 1 sample.
